

- **Why testing matters:**

Testing is important because it finds mistakes in your code before anyone else sees them. It ensures your system works the way you planned and keeps your data accurate.

- **What is asynchronous processing:**

This is a way to run tasks in the background. It allows the system to do work without making the user wait for it to finish.

- **Important test cases:**

These are specific tests you run to make sure your features work. For example, you check if a registration is blocked when a class is full or if an automated email sends when a student signs up.

- **Async use cases:**

These are the specific areas in your project where you used background tasks. Examples include sending automated confirmation emails or handling large lists of data all at once.

- **Reliability discussion:**

This explains how your choices make the system dependable. It covers how your system handles heavy workloads or complex steps without failing.

- **Reflection:**

This is where you write about what you learned. You explain why using these testing and background processing methods is important for building professional apps.
